

A Behavioral Type System for Memory-Leak Freedom

Qi Tan

Kyoto University
tanki@fos.kuis.kyoto-u.ac.jp

1. Problem and Motivation

In order to prevent dynamic memory management related errors such as memory leaks and illegal read/write/free operations to deallocated memory cells, many static verification techniques have been proposed [1, 5–8, 10].

These analyses proposed so far mainly guaranteed *partial* memory-leak freedom: All the allocated memory cells are deallocated *if a program terminates*. We say a program is *total* memory-leak free if it consumes bounded number of memory cells during execution.

In real-world programs, total memory-leak freedom is an important property (e.g., operating system and Web servers). However, partial memory-leak freedom is not enough for such software that does not terminate. See Figure 1.

<pre> 1 h()= 2 let x = malloc() in 3 let y = malloc() in 4 free(x); free(y); h()</pre>	<pre> 1 h'()= 2 let x = malloc() in 3 let y = malloc() in 4 h'(); free(x); free(y)</pre>
--	--

Figure 1. Memory leaks in nonterminating programs.

Example 1.1. Figure 1 describes *partial* and *total* memory-leak freedom. Both h and h' are *partially* memory-leak free because they do not terminate. The function h is *totally* memory-leak free since it consumes at most two cells¹. However, the function h' , when it is invoked, consumes unbounded number of memory cells; hence h' is not *totally* memory-leak free, which may cause overflow.

Currently, we want to guarantee, total memory-leak freedom, that a program consumes bounded number of memory cells during execution.

2. Approach

Our method is to abstract the behavior of programs by *Behavioral type system* [2–4]. Behavioral types are described by sequential processes whose actions represent memory allocation and deallocation. For example, our type system can assign a type $\mu\alpha.\text{malloc};\text{malloc};\text{free};\text{free};\alpha$ to the function h in Figure 1. This type expresses that h can allocate a memory cell twice, deallocate a memory cell twice, and then iterate this behavior. The type assigned to h' in Figure 1 is $\mu\alpha.\text{malloc};\text{malloc};\alpha;\text{free};\text{free}$, which expresses that h' can allocate a memory cell twice, call itself recursively, and then deallocate a memory cell twice. Hence, by inspecting the inferred types (for example, by using some model checkers), one can estimate the upper bound required to execute h and h' .

Notice that, our behavioral type system only about the number and the order of allocations, deallocations and recursive calls;

hence, the type system does not guarantee that illegal accesses to a dangling pointer. However, combining some safe-memory-deallocation analyses, for example, proposed by Suenaga and Kobayashi [6], with our behavioral type system, we can verify safe-memory-deallocation even for nonterminating programs.

2.1 Language

The definition of the language is as follows; It is a sublanguage of Suenaga and Kobayashi [6].

$$\begin{aligned}
 s \text{ (statements)} \quad ::= & \text{skip} \mid s_1; s_2 \mid *x \leftarrow y \\
 & \mid \text{free}(x) \mid \text{let } x = \text{malloc}() \text{ in } s \\
 & \mid f(\vec{x}) \mid \text{ifnull}(x) \text{ then } s_1 \text{ else } s_2 \\
 & \dots
 \end{aligned}$$

The command **skip** does nothing; the sequence $s_1; s_2$ means the executing order of s_1 and s_2 ; the command **free**(x) deallocates the memory cell through the pointer x ; and the command **let** $x = \text{malloc}()$ **in** s first allocates a memory cell which is pointed by x and then executes s ; $f(\vec{x})$ means a function call which receives some parameters. Here \vec{x} means that $\{x_1, \dots, x_n\}$, the list of distinct variables; **ifnull**(x) **then** s_1 **else** s_2 executes s_1 if x is **null**, otherwise s_2 .

A program *leaks* memory if the program consumes unbounded number of memory cells. For example, see Figure 1 again, h does not leak memory, whereas h' does; the former consumes at most two memory cells at once but the latter consumes unbounded number of memory cells.

2.2 Behavioral Type System

We define behavioral types, CCS-like processes that abstract the behavior of programs, as follows:

$$\begin{aligned}
 P \text{ (behavioral types)} \quad ::= & \mathbf{0} \mid P_1; P_2 \mid P_1 + P_2 \\
 & \mid \text{malloc} \mid \text{free} \mid \alpha \mid \mu\alpha.P \\
 \Gamma \text{ (variable type environments)} \quad ::= & \{x_1, x_2, \dots, x_n\} \\
 \Theta \text{ (function type environments)} \quad ::= & \{f_1 : P_1, \dots, f_n : P_n\}
 \end{aligned}$$

The type $\mathbf{0}$ is the behavior “does nothing”; $P_1; P_2$ is for sequential execution; $P_1 + P_2$ is for choice; **malloc** is the behavior of a program that allocates a memory cell exactly once; **free** is for deallocating exactly once; $\mu\alpha.P$ is the recursive type. For example, the body of the function f has the type $\mu\alpha.\text{malloc}; \text{free}; \alpha$ and the body of g has $\mu\alpha.\text{malloc}; \alpha; \text{free}$. The semantics of behavioral types is given by a labeled transition system, which is omitted in this abstract.

The type judgment of our type system is of the form $\Theta; \Gamma \vdash s : P$. It reads “under environments Θ and Γ the behavior of s is as described in P ”. We design the type system so that $\Theta; \Gamma \vdash s : P$ implies the following property:

When s executes **malloc** (resp. **free**), then P is equivalent to **malloc**; P' (resp. **free**; P') for a type P' such that $\Theta; \Gamma \vdash s' : P'$, where s' is the continuation of s .

¹ We assume that every memory cell allocated by **malloc** is fixed size to simplify our type system.

$$\begin{array}{c}
\frac{}{\Theta; \Gamma \vdash \text{free}() : \text{free}} \quad (\text{T-Free}) \\
\frac{}{\Theta; \Gamma \vdash s : P} \quad (\text{T-Malloc}) \\
\hline
\Theta; \Gamma \vdash \text{let } x = \text{malloc}() \text{ in } s : \text{malloc}; P
\end{array}$$

Figure 2. Typing rules for `free()` and `malloc()`

This property guarantees that the behavioral type soundly abstracts the upper bound of the consumed memory cells.

We present two typing rules. The rule T-Free represents that the behavior of `free()` is `free`. The rule T-Malloc represents that `let x = malloc() in s` has the behavior `malloc()`; P , where P is the behavior of s .

3. Experiment

In Figure 3, orange bar represents time spent by applying a model checker on original programs; light blue bar shows the time spent by applying a model checker on programs which represents abstracted behavioral types. we can observe that our approach, the latter one, is more efficient than the former.

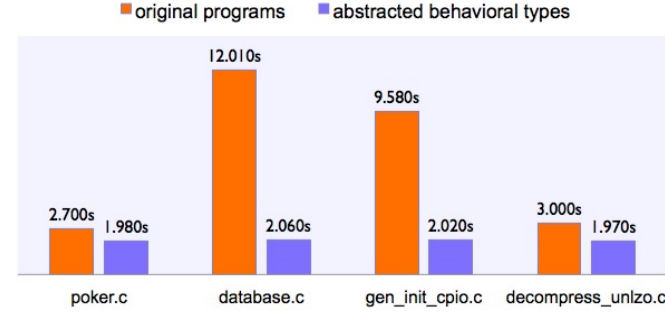

Figure 3. Time spent by a model checker

	original programs	abstracted behavior
	Result of verification	Result of verification
poker.c	Success	Fail
database.c	Success	Fail
gen_init_cpio.c	Success	Fail
decompress_unlzo.c	Success	Fail

Figure 4. Verification of total memory-leak free

3.1 Accuracy

From Figure 4, we observe that verification by applying a model checker on original programs is Success (total memory-leak free), however, verification on our approach is Fail.

The reason is that our method is not path-sensitive, and it simply rejects the programs which allocate cells before recursive calls. We have checked many of source codes from Github and Linux kernel and found that extending our behavioral type system with dependencies is useful for our future work.

4. Related Works

Many static verification methods have been proposed [1, 5–8, 10] for memory-leak freedom. These methods guarantee partial memory-leak freedom and no illegal accesses to deallocated cells, whereas our behavioral type system guarantees total memory-leak

freedom. By using both their methods and our type system, we can guarantee safe-memory-deallocation even for nonterminating programs.

Behavioral types are extensively studied in the context of concurrent program verification [2–4, 9]. Our type system is largely inspired by one proposed by Kobayashi et al. [4], which guarantees that a concurrent program accesses resources according to specification.

5. Conclusion

To verify memory-leak freedom for possibly nonterminating programs, we proposed a behavioral type system which abstracts the behavior of programs with allocation and deallocation. We proved the type soundness and conducted experiments to check feasibility of our approach.

6. Future Direction

The allocation primitives defined in our type system ignore the size of the allocated block for simplification. Hence, a memory-leak program may be checked well-typed by our approach. Variable-length cells will be included in our future work. Another feature should be considered is path-sensitive, because abstracted behavior types are not enough to check memory-leak freedom. For accuracy, we are going to extend our type system with dependencies.
